

The online database holds the structure and style of the website. It pings information (like current inventory) from the MAS database.

This is done by having certain data fields within the online database scripted to XML.

Examples of these fields are: shipping information, customer information, purchase information, etc.

1. User inputs order information
2. Host requests verification
3. Verification confirmed
4. Order placed
5. Order confirmed
6. Confirmed orders requested via XML by MAS 200

XML Output:

1. XML file pinged by MAS 200
2. Orders submitted to MAS SQL
3. MAS accesses information (shipping sent to Starship)
4. MAS returns updated information (updated inventory, shipping information)
